CARE OF WATER METERS

It has been the experience of the Water Department of the Village that considerable unnecessary expense to residents is caused every year during cold weather by their failure to properly protect the water meter installed in the basement. Rule No. 26 of the Water and Light Department carries the following provision:

"No person taking water from the waterworks of the Village shall permit his service pipe or fixtures connected therewith to be out of good repair or unprotected from frost. He also must provide ample protection against damage to the meter from any cause whatever and maintain its location convenient and accessible for inspection and removal."

Water meters are damaged from two causes: namely, frost and hot water.

There is little danger from damage by frost in the case of meters installed in basements, as ordinarily the basement temperature seldom falls below freezing. The principal danger lies in the possibility of a basement window being blown open during a heavy storm and allowing the meter to freeze before it is discovered. Household holders should therefore see that all basement windows are properly secured before the advent of extremely cold weather.

Damage from hot weather is caused by boiling water being forced back through the meter against the pressure in the mains, as a result of over-heated water heaters, connected to the heating plant of the building. Hot water damage the rubber composition disc of the meter and also the celluloid dials, and necessitates expensive repairs.

No entirely satisfactory method of protecting the meter against this sit-

uation has been devised, although there are a number of combinations of check valves and relief valves on the market which are fairly reliable, but rather expensive to install.

Careful operation of the heating plant, during extremely cold weather, will obviate the necessity of the consumer paying for repairs to meters damaged by hot water. The trouble always occurs when the furnace is being forced to adequately heat the house on days when the temperature is very low. When the water in the tank is raised to boiling temperature, the movement of the steam and hot water back through the water service pipe causes a very audible pounding noise which is easily noticed. As soon as this occurs, water should be drawn

from the hot water faucet so that cold water may be admitted to reduce the temperature. A little attention to this matter on very cold days may result in a considerable saving to the Building permits totaling \$61,000

These matters are called to the attention of our residents at this time in order that they may not be held liable for unnecessary expense under Rule 26, particularly at this time when

the need of economizing in every way is of paramount importance.
